

Modelling for beginners

—
Dr Trish Campbell
Senior Research Fellow, Doherty Institute

**Immunisation Coalition
Annual Scientific Meeting**
6/7 February 2022

What are models?

- A model is a simplified representation of the world
- Infectious disease models help us understand patterns of disease by representing the **dynamic process** by which they spread (using equations and/or computational algorithms)

The classic SIR model

The Susceptible, Infectious, Recovered (SIR) model is one of the simplest disease models, proposed almost 100 years ago¹ and still the basis of infectious disease modelling today.

The SIR model sorts individuals into three compartments based on their disease state:

Susceptible – can be infected

Infectious – can infect others

Recovered (or Removed) – cannot be infected nor infect others

[1] Kermack, WO & McKendrick, AG.(1927). *Proceedings of the Royal Society A*. 115(772): pp 700–721.

SIR model: sorting individuals

- A major assumption of the classic SIR compartmental infectious disease model is that individuals **only** differ by their disease state

SIR model: sorting individuals

- A major assumption of the classic SIR compartmental infectious disease model is that individuals **only** differ by their disease state

SIR model: sorting individuals

- A major assumption of the classic SIR compartmental infectious disease model is that individuals **only** differ by their disease state

SIR model: sorting individuals

- A major assumption of the classic SIR compartmental infectious disease model is that individuals **only** differ by their disease state

SIR model: grouping individuals

Since the only difference between individuals in our population is their disease status, we can group all of the individuals with the same disease status together.

SIR model: model schematic

- We consider the events that occur that cause individuals to change their disease state
- We use differential equations to track how the population in each compartment is changing

Adding complexity to the SIR model

- The classic SIR model forms the basis of many infectious disease models.
- To match real world scenarios, it is almost always necessary to add complexity to models.

What information do we need to build transmission models?

Natural history of the disease
e.g.
transmissibility;
latent period;
infectious period;
immunity

Population characteristics and behaviours
e.g. size; age distribution;
number of contacts; risk groups

Treatments and interventions
e.g. coverage;
effectiveness;
type of impact

The **effective** reproduction number (R_{eff})

The time-varying expected number of secondary cases produced by a single (typical) infection in a population that is **not fully-susceptible** to infection

Modelling COVID-19 in Australia

Two examples from the Doherty Modelling Group

Preparedness modelling: early 2020

- SIR-like compartmental model
- Infected but not infectious (E)
- Pre-symptomatic infectiousness (I_1)
- Interventions: Quarantine (dashed) & Isolation (M)

- Unlike the preparedness modelling, the transition modelling used an individual-based model

Transitioning Australia's COVID-19 response: mid-2021

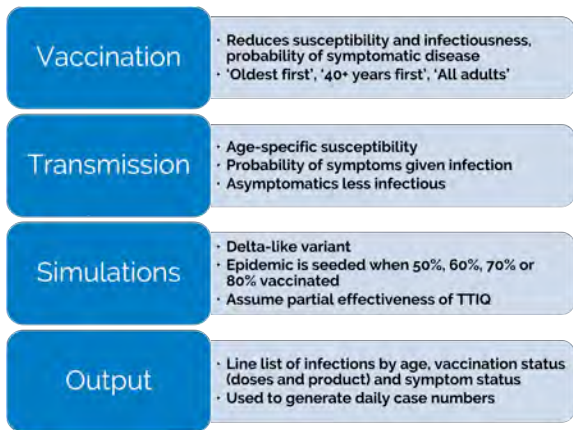

- Unlike the preparedness modelling, the transition modelling used an individual-based model
- With an individual-based model, we do not group individuals by status, but explicitly model their characteristics

Transitioning Australia's COVID-19 response: mid-2021

- Mathematical and computational models for COVID-19 have helped us to understand what measures are required to minimise the consequences of COVID-19 transmission
- COVID-19 is a rapidly changing situation, and we need to be continually updating models as new information becomes available
- The models described here represent epidemiologic modelling of scenarios used to ask 'what if' particular actions were taken — they are **NOT** predictive forecasts

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

$$\frac{dS}{dt} = -\beta IS$$

$$\frac{dI}{dt} = \beta IS - \gamma I$$

$$\frac{dR}{dt} = \gamma I$$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

$$\begin{aligned}\text{rate of change in S} &\longrightarrow \frac{dS}{dt} = -\beta IS \\ \frac{dI}{dt} &= \beta IS - \gamma I \\ \frac{dR}{dt} &= \gamma I\end{aligned}$$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

$$\text{rate of change in S} \longrightarrow \frac{dS}{dt} = -\beta IS$$

$$\text{rate of change in I} \longrightarrow \frac{dI}{dt} = \beta IS - \gamma I$$

$$\frac{dR}{dt} = \gamma I$$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

rate of change in S $\longrightarrow \frac{dS}{dt} = -\beta IS$

rate of change in I $\longrightarrow \frac{dI}{dt} = \beta IS - \gamma I$

rate of change in R $\longrightarrow \frac{dR}{dt} = \gamma I$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

rate of change in S $\rightarrow \frac{dS}{dt} = -\beta IS$ ← rate of new infections

rate of change in I $\rightarrow \frac{dI}{dt} = \beta IS - \gamma I$

rate of change in R $\rightarrow \frac{dR}{dt} = \gamma I$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.

SIR model: Ordinary Differential Equations

The rules governing the transfer of the population between the Susceptible (S), Infectious (I) and Recovered (R) compartments are established by a set of differential equations:

$$\begin{aligned} \text{rate of change in S} &\longrightarrow \left(\frac{dS}{dt}\right) = -\beta IS \longleftarrow \text{rate of new infections} \\ \text{rate of change in I} &\longrightarrow \left(\frac{dI}{dt}\right) = \beta IS - \gamma I \longleftarrow \text{rate of recoveries} \\ \text{rate of change in R} &\longrightarrow \left(\frac{dR}{dt}\right) = \gamma I \end{aligned}$$

where β is the per capita rate of effective contact between two individuals and γ is the reciprocal of the duration of infectiousness.
